

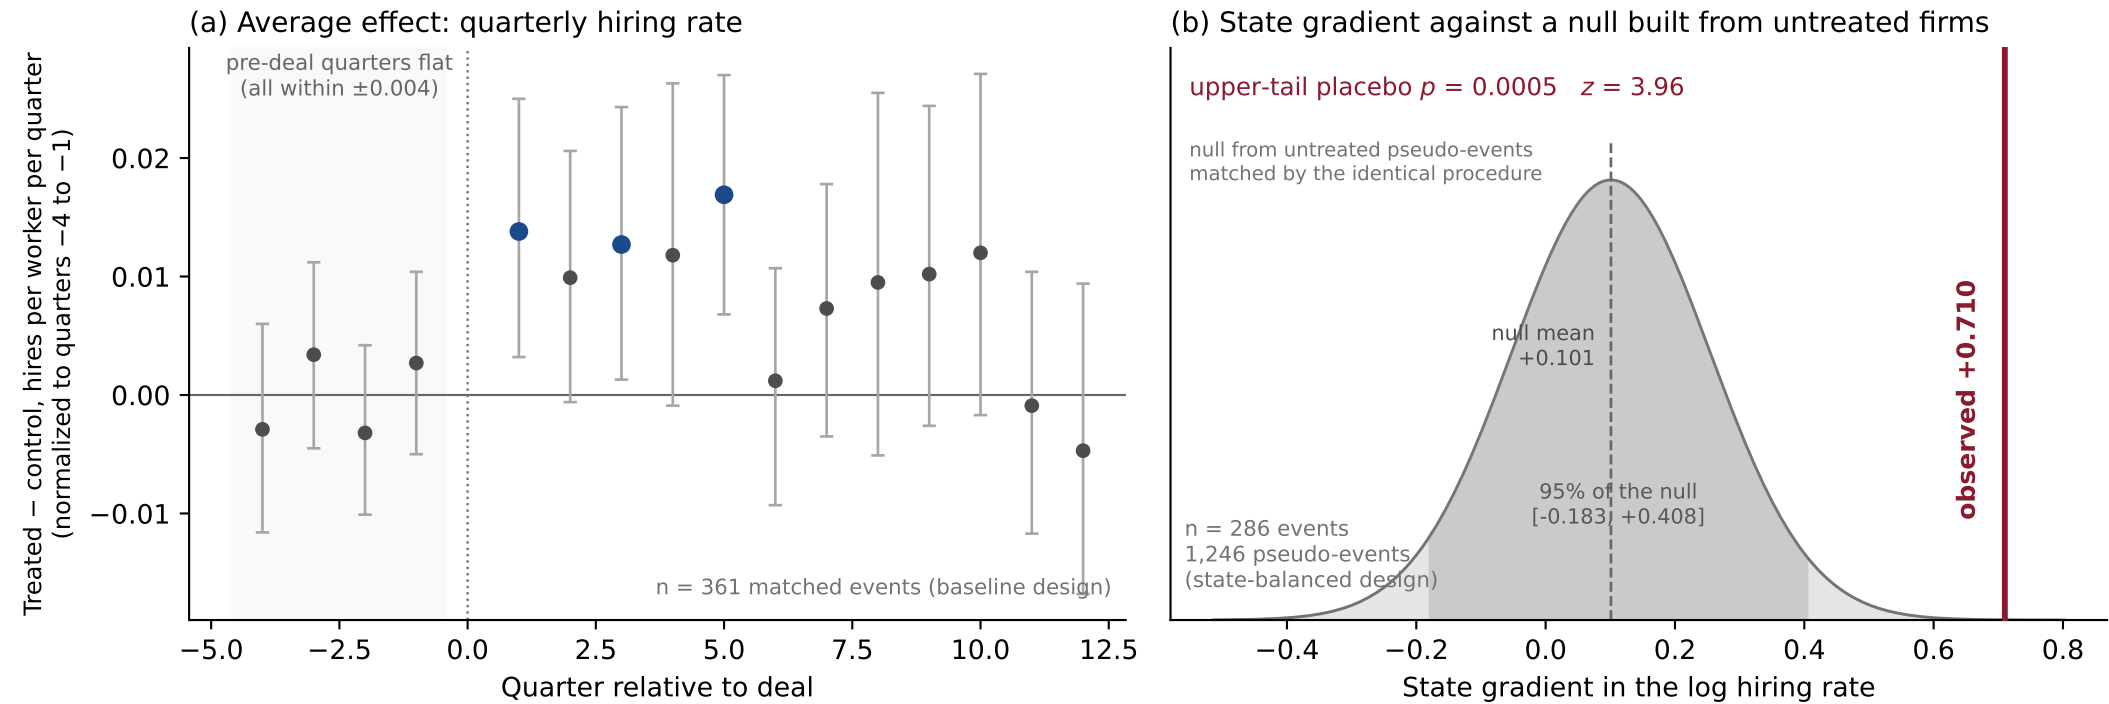

Figure 1. Hiring rises after the deal, and the response is concentrated in targets with low pre-deal hiring intensity

Panels use different samples and outcomes: (a) is the average effect on the quarterly hiring rate in the baseline matched design; (b) is the state gradient in the log hiring rate in the state-balanced design. Intervals in (a) are event-bootstrap; the distribution in (b) is the placebo null, not a confidence interval. In (a), $n = 361$ is the number of events with all four pre-deal quarters observed; contributing events decline with horizon, from 353 at quarter 1 to 249 at quarter 12.
